

Discussion of

Faiella and Lavecchia:

**Households' energy demand and carbon taxation in Italy**

Jirka Slacalek

European Central Bank  
[www.slacalek.com](http://www.slacalek.com)

ECB workshop on fiscal policy and climate change

The views expressed are mine  
and do not necessarily reflect those of the ECB.

# Key contributions

## What the paper does

- ▶ Estimate demand elasticity of energy components in Italian micro data ...
- ▶ ... allowing for differences across electricity/heating/transport & households
- ▶ Simulate effects of carbon taxes on energy demand and emissions

## Results

- ▶ Energy elasticities: roughly  $-0.4$  in short run (monthly),  $-1.2$  in long run
- ▶ Carbon taxation is regressive
- ▶ Poorer households respond somewhat more strongly to carbon taxes:
  - ▶ Reduce electricity and transport fuels demand by 50–60% more
  - ▶ Still face higher  $\uparrow$  total consumption (energy makes up higher share of their total C)

# Key contributions

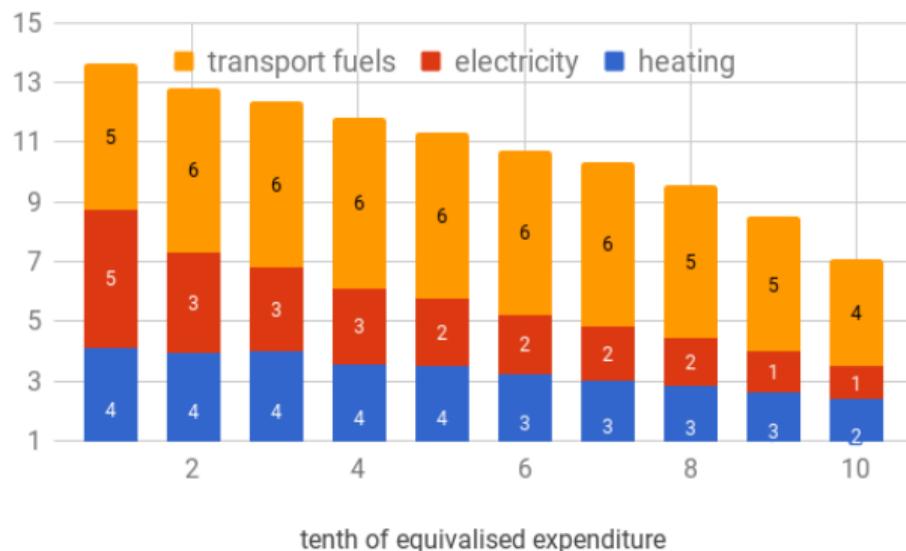

## What the paper does

- ▶ Estimate demand elasticity of energy components in Italian micro data ...
- ▶ ... allowing for differences across electricity/heating/transport & households
- ▶ Simulate effects of carbon taxes on energy demand and emissions

## Results

- ▶ Energy elasticities: roughly  $-0.4$  in short run (monthly),  $-1.2$  in long run
- ▶ Carbon taxation is regressive
- ▶ Poorer households respond somewhat more strongly to carbon taxes:
  - ▶ Reduce electricity and transport fuels demand by 50–60% more
  - ▶ Still face higher  $\uparrow$  total consumption (energy makes up higher share of their total C)

# Italian micro data: energy share by consumption decile

- ▶ Monthly time series of detailed micro data on consumption items, HBS 1997–2018
- ▶ Households in top decile have 50% lower energy share on total C (because of electricity and heating): 7% vs 14%

## Estimation specification

Regression of energy quantity of group  $s$   $Q_{s,t}^z$  on its price  $P_t^z$ :

$$\log Q_{s,t}^z = \lambda_s \log Q_{s,t-1}^z + \beta_s \log P_t^z + \text{controls}_{s,t} + \epsilon_{s,t}$$

- ▶  $\beta_s$  short-run price elasticity of energy demand
- ▶  $\beta_s/(1 - \lambda_s)$  long-run elasticity
- ▶ Controls include total consumption
- ▶ Can be estimated for each group (quasi-panel, 36 groups)
- ▶ OLS and IV (instrumented with wholesale prices)

## Estimation results: energy elasticities

	Short run price elasticities			long run
	LS	stratum-level LS	2SLS	
Electricity	-0.36***	-0.29*	-0.40***	-1.17***
Heating	-0.40***	-0.44**	-0.44***	-1.23***
Transport	-0.17**	-0.45**	-0.66***	-1.46***

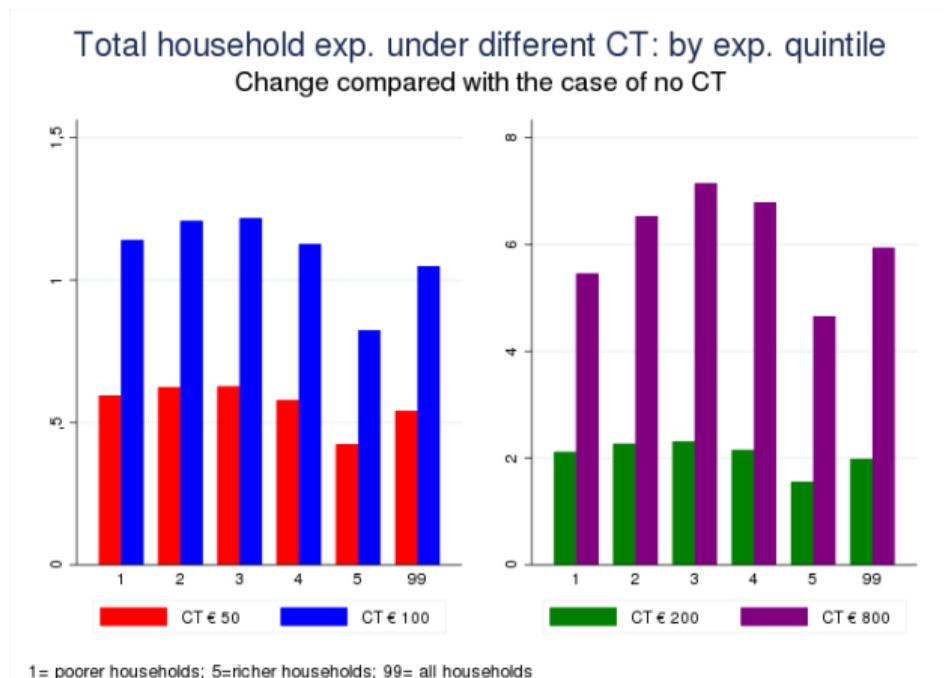

\*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$

Table 3: Price elasticities

- ▶ **Elasticities:** around  $-0.4$  in short run (monthly), b/w  $-1.5$  and  $-1.2$  in long run
- ▶ **Poorer households respond more strongly to higher prices:**  
Reduce electricity and transport fuels demand by 50–60% more (response of heating similar across households)

# Simulation results: regressive impact of carbon taxes

- ▶ How do households respond to carbon tax? (EUR 50–EUR 200 per ton of CO<sub>2</sub>)  
EUR 50 per ton  $\Rightarrow$  6% increase in price of electricity (0.7% in HICP inflation)
- ▶ Poorer households cut energy demand more, but still face higher increase in total consumption expenditures (energy makes up higher share of their total C)

# Comments

# Comment 1: Estimated demand elasticity is quite high

Labandeira et al. (2017): short-run  $-0.2$ , long-run  $-0.5$

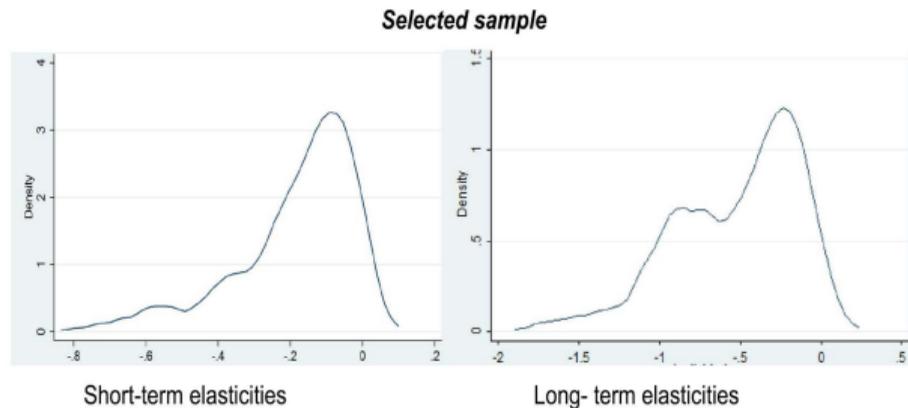

Fig. 1. Density of the price elasticities. Total and selected samples.

**Table 6**

Average energy products elasticities in the empirical literature.

	Short term	Long term
<b>Electricity</b>	<b><math>-0.126^*</math></b>	<b><math>-0.365^*</math></b>
<b>Natural Gas</b>	<b><math>-0.180^{***}</math></b>	<b><math>-0.684^*</math></b>
<b>Gasoline</b>	<b><math>-0.293^{***}</math></b>	<b><math>-0.773^{***}</math></b>
<b>Diesel</b>	<b><math>-0.153^{**}</math></b>	<b><math>-0.443^{***}</math></b>
<b>Heating oil</b>	<b><math>-0.017</math></b>	<b><math>-0.185</math></b>

\*\*\* Significant at the 1% level.

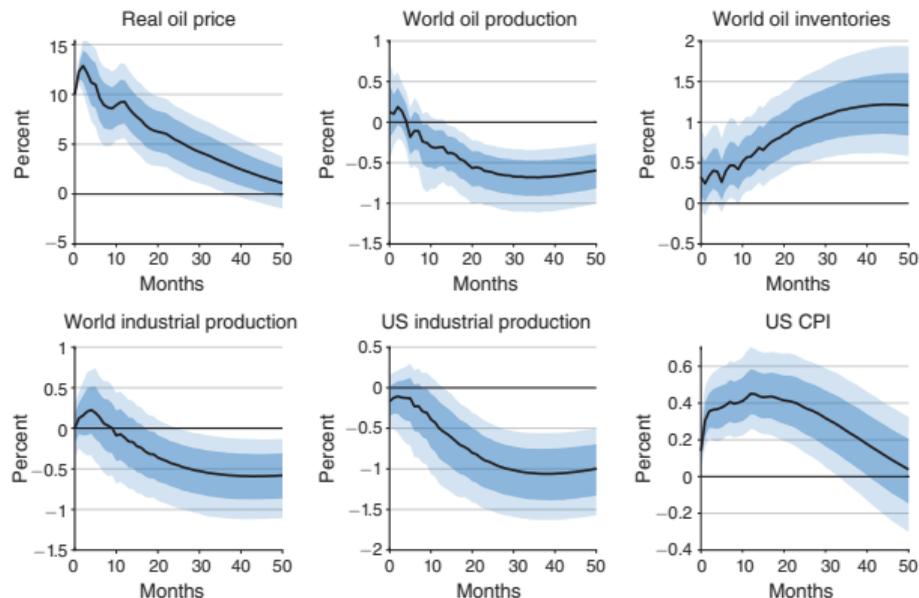

## Comment 2: Price level vs price surprises

$$\log Q_{s,t}^z = \lambda_s \log Q_{s,t-1}^z + \beta_s \log P_t^z + \text{controls}_{s,t} + \epsilon_{s,t}$$

- ▶ Estimation is in levels
- ▶ Prices are persistent  $\Rightarrow$  substantial(?) part of price changes are expected
- ▶ Should estimate regression in differences (as check)

### 3: Focus on one partial equilibrium channel of energy prices

- ▶ Energy prices affect households also via **general equilibrium effects**  
eg lower aggregate demand and employment (skewed toward some sectors)
- ▶ Känzig (AER, 2021) aggregate evidence

First-stage regression:  $F$ : 22.67, robust  $F$ : 10.55,  $R^2$ : 4.22%, Adjusted  $R^2$ : 4.04%

FIGURE 3. IMPULSE RESPONSES TO AN OIL SUPPLY NEWS SHOCK

## Comment 4: Quibbles about estimation

$$\log Q_{s,t}^z = \lambda_s \log Q_{s,t-1}^z + \beta_s \log P_t^z + \text{controls}_{s,t} + \epsilon_{s,t}$$

- ▶ Dynamic panel: Should use Arellano Bond (1991)
- ▶ Quasi-panel (unfortunately HBS is not panel): Should check that there are limited movements between groups
- ▶ HBS collects data on expenditures  $\Rightarrow P_t^z$  not group-specific (measurement error)
- ▶ Limited information on control variables in HBS (no income, wealth)
- ▶ Should include time fixed effects, (perhaps) drop time trends

# Summary

- ▶ Nice, timely work with detailed micro data
- ▶ Very relevant currently, with high/volatile energy prices
- ▶ How does elasticity differ at high levels of energy prices?  
Elasticity even higher in very long run?
